

The Design of C: A Rational Reconstruction (cont.)

Goals of this Lecture

- Recall from last lecture...
- Help you learn about:
 - The decisions that were **available to** the designers of C
 - The decisions that were **made by** the designers of C
 - ... and thereby...
 - C !
- Why?
 - Learning the design rationale of the C language provides a richer understanding of C itself
 - ... and might be more interesting than simply learning the language itself !!!
 - A power programmer knows both the programming language and its design rationale

Character Data Types

- Issue: What character data types should C have?
- Thought process
 - The most common character codes are (were!) ASCII and EBCDIC
 - ASCII is 7-bit
 - EBCDIC is 8-bit
- Decisions
 - Provide type **char**
 - Type **char** should be one byte

Was that a good decision?

Character Data Types (cont.)

- Tangential Decision

- **char** should be an integer type

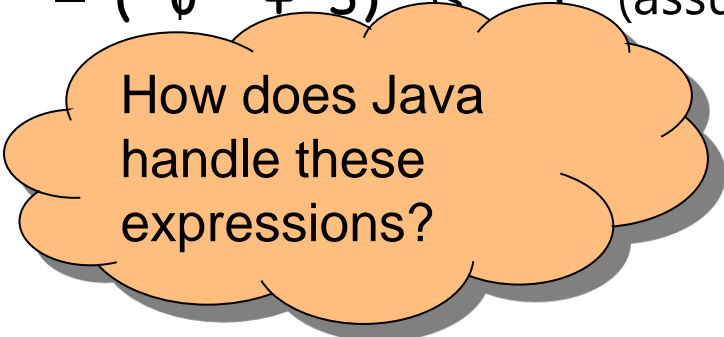

- Can use type **char** to store small integers

- Can do arithmetic with data of type **char**

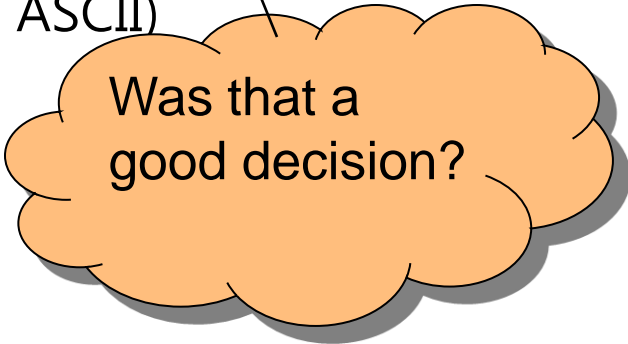

- Can freely mix **char** and integer data

- ('a' + 1) is 'b' (assuming ASCII)

- ('0' + 5) is '5' (assuming ASCII)

How does Java handle these expressions?

Was that a good decision?

Character Constants

- Issue: How should C represent character constants?
- Thought process
 - Could represent character constants as `int` constants, with truncation of high-order bytes
 - More readable to use single quote syntax (`'a'`, `'b'`, etc.); but then...
 - Need special way to represent the single quote character
 - Need special ways to represent non-printable characters (e.g. newline, tab, space, etc.)
- Decisions
 - Provide single quote syntax
 - Use backslash to express special characters

Character Constants (cont.)

- Examples

- `'a'` **the a character**
- `(char) 97` the a character
- `(char) 0141` the a character
- `'\o141'` the a character, octal character form
- `'\x61'` the a character, hexadecimal character form
- `'\0'` **the null character**
- `'\a'` bell
- `'\b'` backspace
- `'\f'` formfeed
- `'\n'` **newline**
- `'\r'` carriage return
- `'\t'` **horizontal tab**
- `'\v'` vertical tab
- `'\\'` backslash
- `'\''` single quote

Strings

- Issue: How should C represent strings?
- Thought process
 - String can be represented as a sequence of chars
 - How to know where char sequence ends?
 - Store length before char sequence?
 - Store special "sentinel" char after char sequence?
 - Strings are common in systems programming
 - C should be small/simple

Advantages/disadvantages?

Strings (cont.)

- Decisions

- Adopt a convention
 - String consists of a sequence of chars terminated with the null (' \0 ') character
- Use double-quote syntax (e.g. "**abc**", "**hello**") to represent a string constant
- Provide no other language features for handling strings
 - Delegate string handling to standard library functions

- Examples

- "**abc**" is a string constant
- '**a**' is a **char** constant
- "**a**" is a string constant

How many bytes?

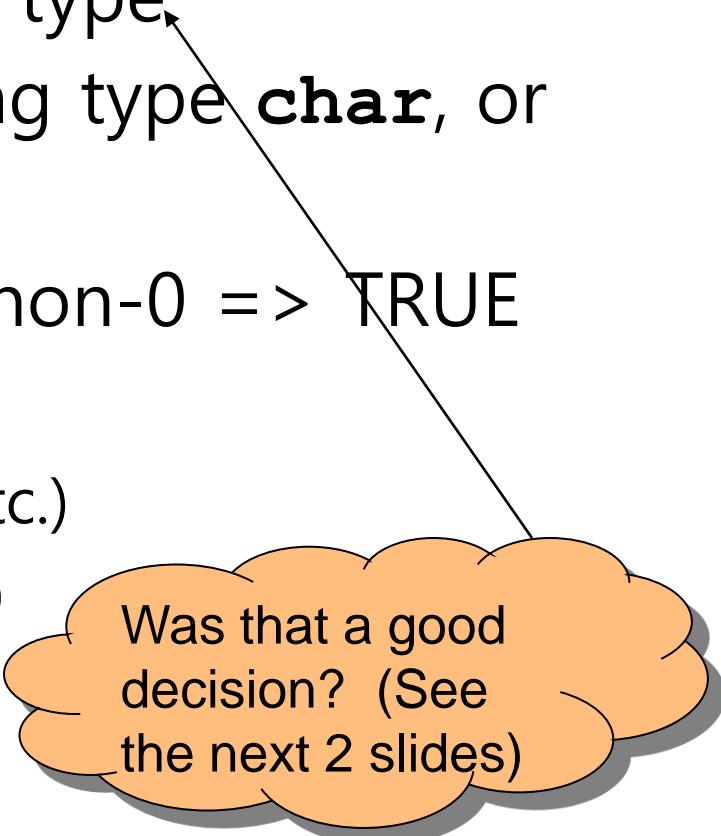

Logical Data Type

- Issue: How should C represent logical data?
- Thought process
 - Representing a logical value (TRUE or FALSE) requires only one **bit**
 - Smallest entity that can be addressed is one **byte**
 - Type **char** is one byte, so could be used to represent logical values
 - C should be small/simple

Logical Data Type (cont.)

- Decisions

- Don't define a logical data type
- Represent logical data using type **char**, or any integer type
- Convention: 0 => FALSE, non-0 => TRUE
- Convention used by:
 - Relational operators (<, >, etc.)
 - Logical operators (!, &&, ||)
 - Statements (**if**, **while**, etc.)

Was that a good decision? (See the next 2 slides)

Logical Data Type (cont.)

- Note

- Using integer data to represent logical data permits shortcuts

```
...  
int i;  
...  
if (i) /* same as (i != 0) */  
    statement1;  
else  
    statement2;  
...
```

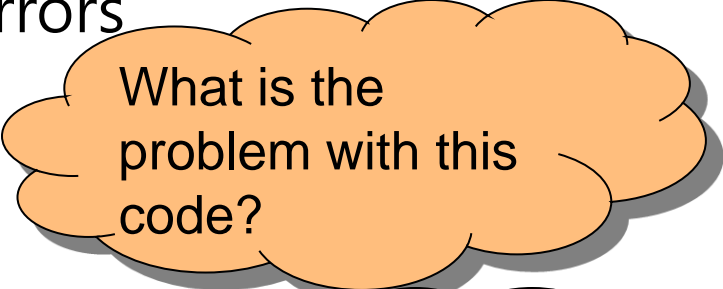

Are such shortcuts beneficial?

Logical Data Type (cont.)

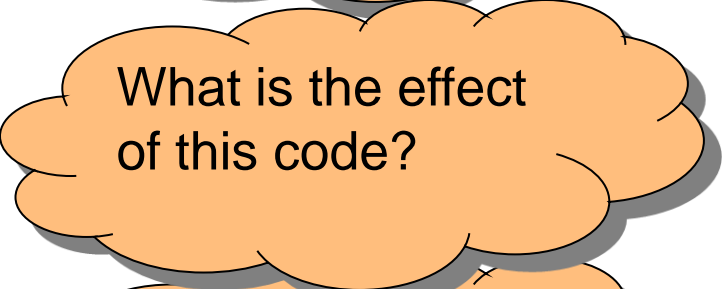

- Note

- The lack of logical data type cripples compiler's ability to detect some errors

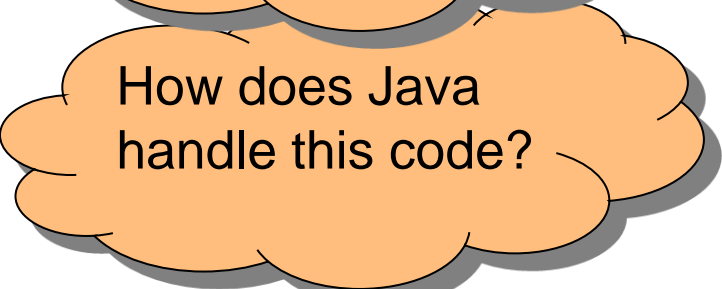

```
...  
int i;  
...  
i = 0;  
...  
if (i = 5)  
    statement1;  
else  
    statement2;  
...
```

What is the problem with this code?

What is the effect of this code?

How does Java handle this code?

Floating-Point Data Types

- Issue: What floating-point data types should C have?
- Thought process
 - Systems programs use floating-point data infrequently
 - But some application domains (e.g. scientific) use floating-point data often
- Decisions
 - Provide three floating-point data types: **float**, **double**, and **long double**
 - bytes in **float** \leq bytes in **double** \leq bytes in **long double**
- Incidentally, on lab machines using gcc209
 - **float**: 4 bytes
 - **double**: 8 bytes
 - **long double**: 12 bytes

Floating-Point Constants

- Issue: How should C represent floating-point constants?
- Thought process
 - Convenient to allow both fixed-point and scientific notation
 - Decimal is sufficient; no need for octal or hexadecimal
- Decisions
 - Any constant that contains decimal point or "E" is floating-point
 - The default floating-point type is **double**
 - Append "F" to indicate **float**
 - Append "L" to indicate **long double**
- Examples
 - **double**: 123.456, 1E-2, -1.23456E4
 - **float**: 123.456F, 1E-2F, -1.23456E4F
 - **long double**: 123.456L, 1E-2L, -1.23456E4L

Why?

Feature 2: Operators

- A high-level programming language should have **operators**
- Operators combine with constants and variables to form expressions

Kinds of Operators

- Issue: What kinds of operators should C have?
- Thought process
 - Should handle typical operations
 - Should handle bit-level programming ("bit fiddling")
- Decisions
 - Provide typical arithmetic operators: `+` `-` `*` `/` `%`
 - Provide typical relational operators: `==` `!=` `<` `<=` `>` `>=`
 - Each evaluates to 0=>FALSE or 1=>TRUE
 - Provide typical logical operators: `!` `&&` `||`
 - Each interprets 0=>FALSE, non-0=>TRUE
 - Each evaluates to 0=>FALSE or 1=>TRUE
 - Provide bitwise operators: `~` `&` `|` `^` `>>` `<<`
 - Provide a cast operator: `(type)`

Assignment Operator

- Issue: What about assignment?
- Thought process
 - Must have a way to assign a value to a variable
 - Many high-level languages provide an assignment **statement**
 - Would be more expressive to define an assignment **operator**
 - Performs assignment, and then evaluates to the assigned value
 - Allows expressions that involve assignment to appear within larger expressions
- Decisions
 - Provide assignment operator: =
 - Define assignment operator so it changes the value of a variable, and also evaluates to that value

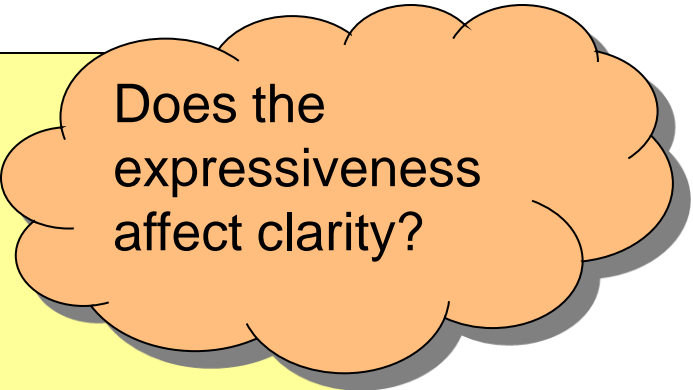

Assignment Operator (cont.)

- Examples

```
i = 0;
/* Assign 0 to i. Evaluate to 0.
   Discard the 0. */

i = j = 0;
/* Assign 0 to j. Evaluate to 0.
   Assign 0 to i. Evaluate to 0.
   Discard the 0. */

while ((i = getchar()) != EOF) ...
/* Read a character. Assign it to i.
   Evaluate to that character.
   Compare that character to EOF.
   Evaluate to 0 (FALSE) or 1 (TRUE). */
```

Does the expressiveness affect clarity?

Increment and Decrement Operators

- Issue: Should C provide increment and decrement operators?
- Thought process
 - The construct `i = i + 1` is common
 - Special purpose increment and decrement operators would make code more expressive
 - Such operators would complicate the language and compiler
- Decisions
 - The convenience outweighs the complication
 - Provide increment and decrement operators: `++` `--`

Was that a good decision?

Special-Purpose Assignment Operators

- Issue: Should C provide special-purpose assignment operators?
- Thought process
 - Constructs such as `i = i + n` and `i = i * n` are common.
 - Special-purpose assignment operators would make code more expressive
 - Such operators would complicate the language and compiler
- Decisions
 - The convenience outweighs the complication
 - Provide special-purpose assignment operators: `+=` `-=` `*=` `/=`
`~=` `&=` `|=` `^=` `<<=` `>>=`

Was that a good decision?

Sizeof Operator

- Issue: How can programmers determine the sizes of data?
- Thought process
 - The sizes of most primitive types are unspecified
 - C must provide a way to determine the size of a given data type programmatically
- Decisions
 - Provide a **sizeof** operator
 - Applied at compile-time
 - Operand can be a **data type**
 - Operand can be an **expression**, from which the compiler infers a data type
- Examples, on lab machines using gcc209
 - **sizeof(int)** evaluates to 4
 - **sizeof(i)** evaluates to 4 (where **i** is a variable of type **int**)
 - **sizeof(i+1)** evaluates to 4 (where **i** is a variable of type **int**)

Other Operators

- Issue: What other operators should C have?
- Decisions
 - Function call operator
 - Should mimic the familiar mathematical notation
 - **function(param1, param2, ...)**
 - Conditional operator: **?:**
 - The only ternary operator
 - See King book
 - Sequence operator: **,**
 - See King book
 - Pointer-related operators: **& ***
 - Described later in the course
 - Structure-related operators (**.** **->**)
 - Described later in the course

Feature 3: Control Statements

- A programming language must provide **statements**
- Some statements must affect flow of control

Control Statements

- Issue: What control statements should C provide?
- Thought process
 - **Boehm** and **Jacopini** proved that any algorithm can be expressed as the nesting of only 3 control structures:

Barry Boehm

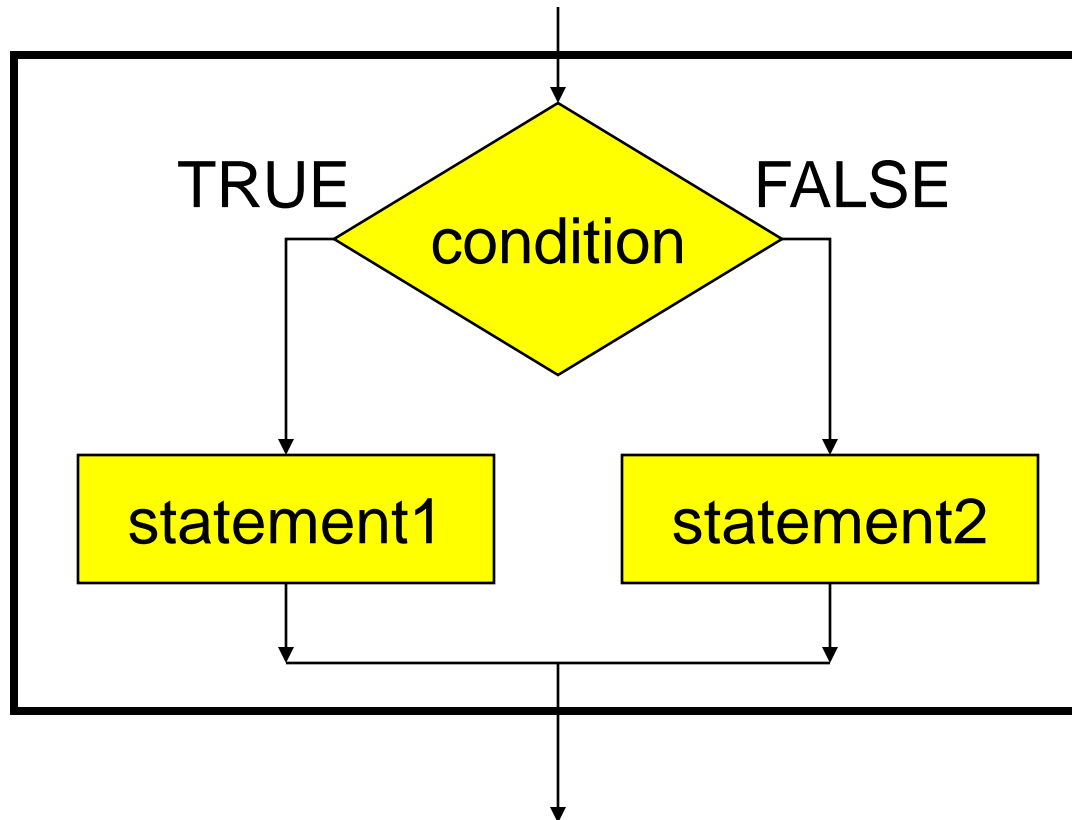

Control Statements (cont.)

(1) Sequence

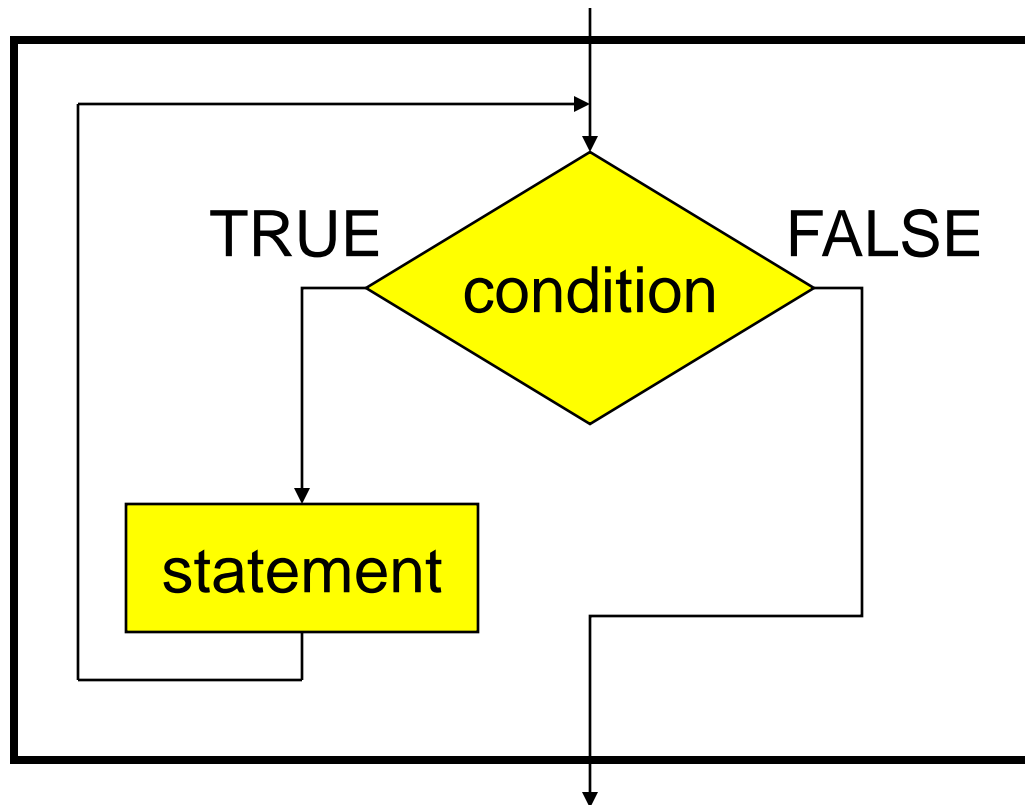

Control Statements (cont.)

(2) Selection

Control Statements (cont.)

(3) Repetition

Control Statements (cont.)

- **Thought Process** (cont.)
 - **Dijkstra** argued that any algorithm **should** be expressed using only those three control structures (*GOTO Statement Considered Harmful* paper)
 - The ALGOL programming language implemented control statements accordingly
- **Decisions**
 - Provide statements to implement those 3 control structures
 - For convenience, provide a few extras

Edsger Dijkstra

Sequence Statement

- Issue: How should C implement sequence?
- Decision
 - **Compound** statement, alias **block**

```
{  
    statement1;  
    statement2;  
    ...  
}
```

Selection Statements

- Issue: How should C implement selection?
- Decisions
 - **if** statement, for one-path or two-path decisions

```
if (integerExpr)  
    statement1;
```

```
if (integerExpr)  
    statement1;  
else  
    statement2;
```

Selection Statements (cont.)

- Decisions (cont.)
 - **switch** and **break** statements, for multi-path decisions

```
switch (integerExpr) {  
  case integerConstant1:  
    ...  
    break;  
  case integerConstant2:  
    ...  
    break;  
  ...  
  default:  
    ...  
}
```

What if these **break** statements are omitted?

Was that use of **break** a good design decision?

Repetition Statements

- Issue: How should C implement repetition?
- Decisions
 - **while** statement, for general repetition

```
while (integerExpr)  
    statement;
```

- **for** statement, for counting loops

```
for (initialExpr; integerExpr; incrementExpr)  
    statement;
```

- **do...while** statement, for loops with test at trailing edge

```
do  
    statement;  
while (integerExpr);
```

Other Control Statements

- Issue: What other control statements should C provide?
- Decisions
 - **break** statement (revisited)
 - Breaks out of closest enclosing **switch** or **repetition** statement
 - **continue** statement
 - Skips remainder of current loop iteration
 - Continues with next loop iteration
 - Can be difficult to understand; generally should avoid
 - **goto** statement and labels
 - Avoid!!! (as per Dijkstra)

Feature 4: Input/Output

- A programming language must provide facilities for reading and writing data
- Alternative: A programming **environment** must provide such facilities

Input/Output Facilities

- Issue: Should C provide I/O facilities?
- Thought process
 - Unix provides the stream abstraction
 - A stream is a sequence of characters
 - Unix provides 3 standard streams
 - Standard input, standard output, standard error
 - C should be able to use those streams, and others
 - I/O facilities are complex
 - C should be small/simple
- Decisions
 - **Do not** provide I/O facilities in C
 - Instead provide a **standard library** containing I/O facilities
 - Constants: **EOF**
 - Data types: **FILE** (described later in course)
 - Variables: **stdin**, **stdout**, and **stderr**
 - Functions: ...

Reading Characters

- Issue: What functions should C provide for reading characters from standard input?
- Thought process
 - Need function to read a single character from **stdin**
 - Function must have a way to indicate failure, that is, to indicate that no characters remain
- Decisions
 - Provide **getchar()** function
 - Make return type of **getchar()** wider than **char**
 - Make it **int**; that's the natural word size
 - Define **getchar()** to return **EOF** (a special non-character **int**) to indicate failure
- Note
 - There is no such thing as "the **EOF** character"

Writing Characters

- Issue: What functions should C provide for writing a character to standard output?
- Thought process
 - Need function to write a single character to **stdout**
- Decisions
 - Provide a **putchar()** function
 - Define **putchar()** to accept one parameter
 - For symmetry with **getchar()**, parameter should be an **int**

Reading Other Data Types

- Issue: What functions should C provide for reading data of other primitive types?
- Thought process
 - Must convert external form (sequence of character codes) to internal form
 - Could provide **getshort()**, **getint()**, **getfloat()**, etc.
 - Could provide one parameterized function to read any primitive type of data
- Decisions
 - Provide **scanf()** function
 - Can read any primitive type of data
 - First parameter is a **format string** containing **conversion specifications**
- See King book for details

Writing Other Data Types

- Issue: What functions should C provide for writing data of other primitive types?
- Thought process
 - Must convert internal form to external form (sequence of character codes)
 - Could provide **putshort()**, **putint()**, **putfloat()**, etc.
 - Could provide one parameterized function to write any primitive type of data
- Decisions
 - Provide **printf()** function
 - Can write any primitive type of data
 - First parameter is a **format string** containing **conversion specifications**
- See King book for details

Other I/O Facilities

- Issue: What other I/O functions should C provide?
- Decisions
 - `fopen()`: Open a stream
 - `fclose()`: Close a stream
 - `fgetc()`: Read a character from specified stream
 - `fputc()`: Write a character to specified stream
 - `fgets()`: Read a line/string from specified stream
 - `fputs()`: Write a line/string to specified stream
 - `fscanf()`: Read data from specified stream
 - `fprintf()`: Write data to specified stream
- Described in King book, and later in the course after covering files, arrays, and strings

Summary

- C's design goals affected decisions concerning language features:
 - Data types
 - Operators
 - Control statements
 - I/O facilities
- Knowing the design goals and how they affected the design decisions can yield a rich understanding of C
